Background

iConquerMS™ is a people-powered research network (PPRN), dedicated to engaging people affected by multiple sclerosis (MS) and researchers in studies on topics that matter to the community. To date, ~4,000 people affected by MS have joined iConquerMS™ and consented to contribute data on the iConquerMS.org portal. In May 2017, a dataset comprising the baseline data provided by participants at the time they join the network (baseline) and at 6-monthly intervals, participants complete a number of surveys, including Demographics, MS Characteristics, the PROMIS® Global Health Survey (GHS), and the Neuro-Qol Adult Short Forms (ASF). In May 2017, a dataset comprising the baseline data provided by approximately 1,800 iConquerMS™ participants was downloaded in order to determine the characteristics of the network members. Here, we present characteristics of the iConquerMS™ network related to Stigma and Satisfaction with Social Roles and Activities.

Objectives

- To characterize responses to the Neuro-Qol ASF domains of Stigma and Satisfaction with Social Roles and Activities.
- To identify factors strongly ($r^2≥0.7$) or moderately strongly ($r^2≥0.5$) correlating with scores in these two domains.

Methods

Standard Symptom, Function and Quality of Life (QoL) Surveys Domains of the Neuro-Qol ASF used in the analyses:

[The indicated domain has (M) 5-point Likert-scale questions] Stigma (8) and Satisfaction with Social Roles and Activities (8).

PROMIS® GHS items used in the analyses:

Pain scale plus nine 5-point Likert-scale questions. See Table 2. Graphical Presentation

We generated bar charts of the proportion of respondents that gave a particular answer to each question in the Stigma or Satisfaction with Social Roles and Activities domains for each MS subtype (CIS: Clinically-Isolated Syndrome, RRMS: Relapsing-Remitting MS, SPMS: Secondary Progressive MS, PPMS: Primary Progressive MS). (Ns for each subtype are shown.) Statistical Analyses

Significant differences in QoL characteristics between pairs of MS subtypes, RRMS, SPMS and PPMS, were calculated by converting each Likert-scale answer to an integer value (1=worst status to 5=best status) followed by a Chi-squared test with: a) the integer values for each of the M questions in each domain; and, b) the average value for each respondent for all questions in a domain.

Figure 3: Example Correlation "HeatMap": Correlation between Stigma and Quality of Life

Conclusions

People with MS experience an increase in Stigma and a decrease in their Satisfaction with Social Roles and Activities as their disability worsens. These experiences are moderately strongly to strongly correlated with the overall physical and mental health of people with MS, and with their overall quality of life. Further research is needed to explore, in detail, the factors associated with these quality of life features.
